# PyGame

---

## LECTURE 1

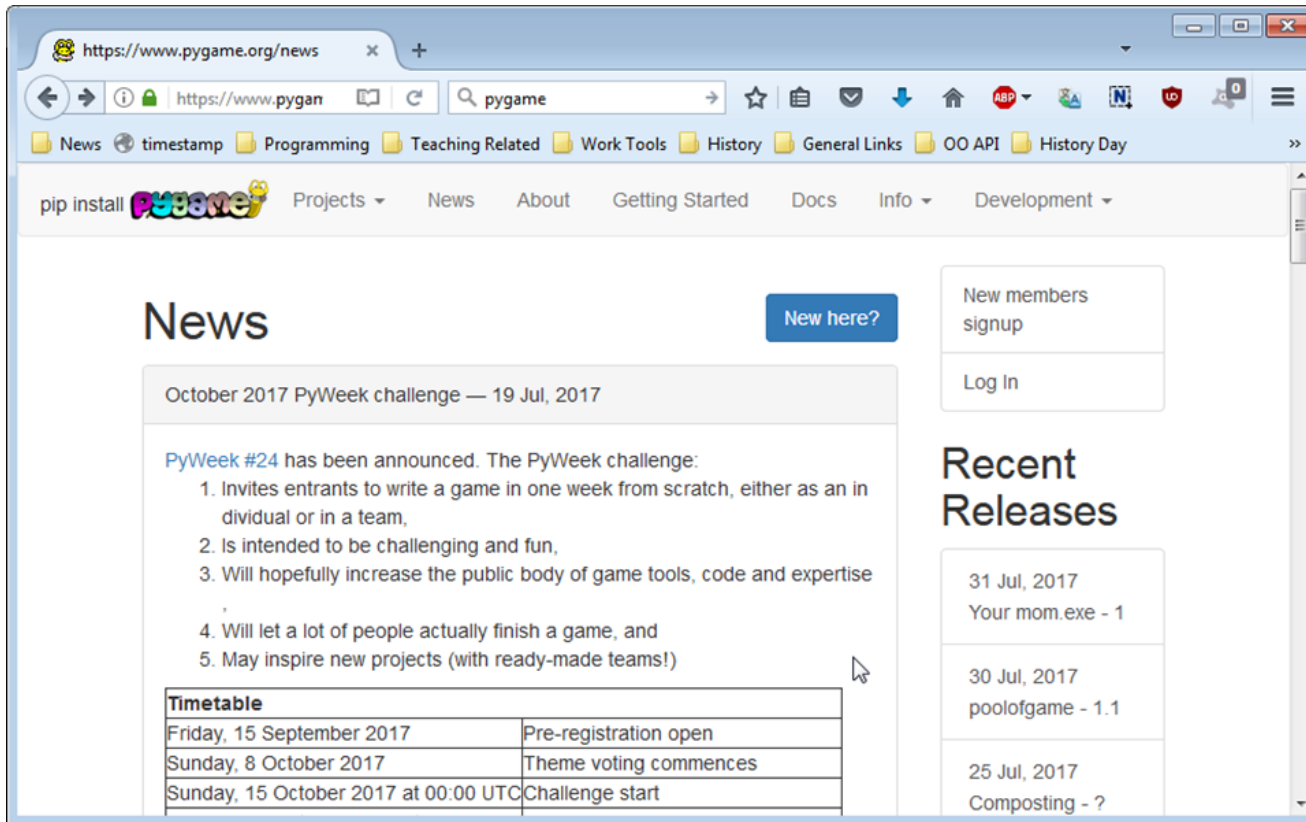

# Objectives

---

- What is PyGame?
- Installing PyGame
- Run "pygameTemplate.py"
- pygameTemplate.py Explained

Let's Learn Python and  
PyGame  
<http://www.pygame.org/>

# What is PyGame?

---

ACTIVITY

# What is Pygame?

---

A set of modules for writing games

- home page: <http://pygame.org/>
- documentation: <http://pygame.org/docs/>

pygame helps you with:

- 2D graphics (and 3D)
- images, sounds, music, (video)
- user input (events) from keyboard, mouse, gamepad
- support for game things
  - sprites, collision detection, etc.

# PyGame Modules

---

The modules include:

cdrom	cursors	display	draw	event
font	image	joystick	key	mixer
mouse	movie	music	overlay	rect
sndarray	sprite	surface	surfarray	
time	transform			

Search page:

- <http://www.pygame.org/docs/search.html>

# Game Things in PyGame

---

**sprites:** moving game characters / objects

**collision detection:** which sprites are touching?

**event:** a user action (e.g. mouse or key press), or computer change (e.g. clock tick)

**game loop:**

- **read** new events
- **update** sprites and game state
- **redraw** game

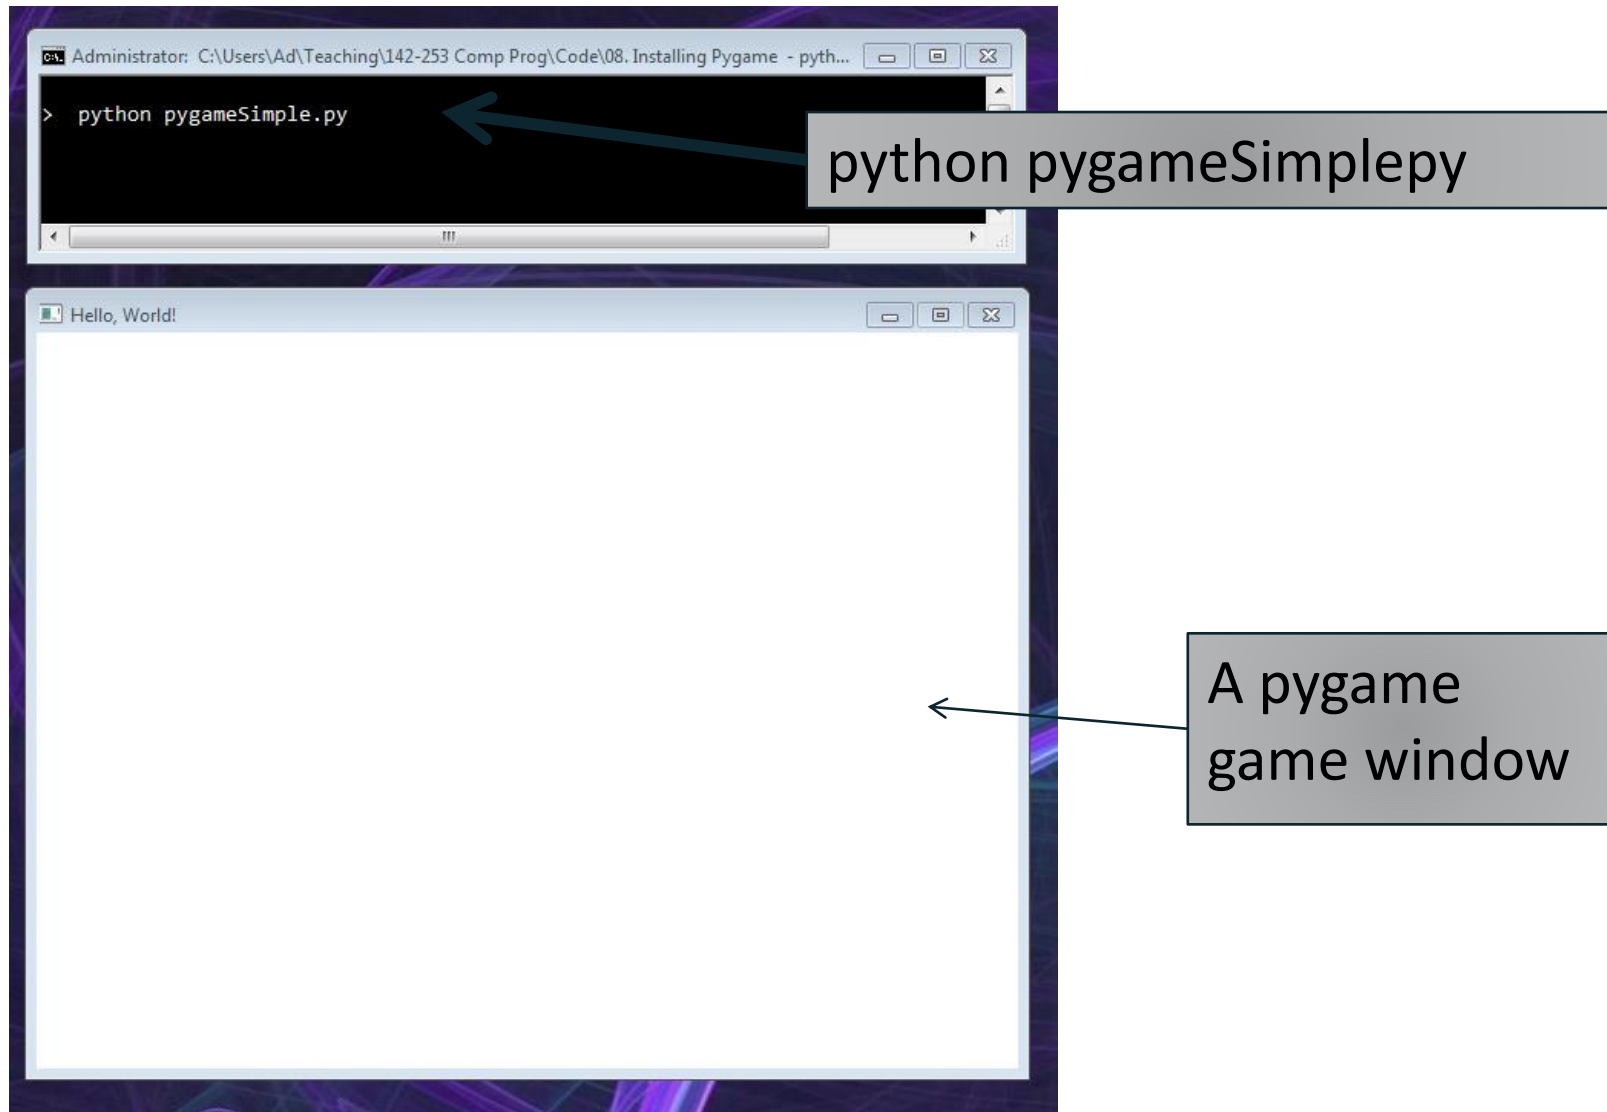

# Run "pygameSimple.py"

---

ACTIVITY

A pygame  
game window

# pygameSimple.py

import pygame
from pygame.locals import *

pygame.init()

screenSize = (640, 480)
screen = pygame.display.set_mode(screenSize)
screen.fill((255,255,255)) # white background

pygame.display.set_caption("Hello, World!") # set title bar

clock = pygame.time.Clock()

running = True
while running: # game loop
    time_passed = clock.tick(30) # set loop speed

    # handle events
    for event in pygame.event.get():
        if event.type == QUIT: # user clicks close box
            running = False

    # update game state (nothing yet)

    # redraw game
    pygame.display.update()

pygame.quit()

Ln: 2 Col: 17
```

# pygameSimple.py Explained

---

ACTIVITY

# pygameSimple.py Explained

```
import pygame
from pygame.locals import *
pygame.init()
screenSize = (640, 480)
screen = pygame.display.set_mode(screenSize)
screen.fill((255,255,255))      # white background
pygame.display.set_caption("Hello, World!")  # set
title bar
clock = pygame.time.Clock()
:
:
```

**EVERY** game program adds to this one. Make sure you understand it.

```
running = True

while running:  # game loop

    clock.tick(30)  # set loop speed

    # handle events

    for event in pygame.event.get():

        if event.type == QUIT: #user clicks close box

            running = False

    # update game state (nothing yet)

    # redraw game

    pygame.display.update()
```

- 
- A blue curved arrow starts from the bottom of the list, goes up and to the left, and points to the 'game loop:' header, indicating a continuous cycle.
- **game loop:**
    - read new events
    - update sprites and game state
    - redraw game

# Creating a Pygame Window

---

```
screen = pygame.display.set_mode( (640, 480) )
```

set\_mode() can take three arguments:

- (width,height), flag(s), bit-depth
  - flags let the window become full-screen and resizable
  - bit-depth sets the number of colors that can be used

# PyGame Colors

```
# white background  
screen.fill( (255, 255, 255) )
```

A color is made from three integers (0-255) for the amount of red, green, and blue (RGB):

- 0 means "no color"
- 255 means "maximum color"
- e.g. (0,0,0) means "black"

<b>Color</b>	<b>RGB Values</b>
Aqua	( 0, 255, 255)
Black	( 0, 0, 0)
Blue	( 0, 0, 255)
Fuchsia	(255, 0, 255)
Gray	(128, 128, 128)
Green	( 0, 128, 0)
Lime	( 0, 255, 0)
Maroon	(128, 0, 0)
Navy Blue	( 0, 0, 128)
Olive	(128, 128, 0)
Purple	(128, 0, 128)
Red	(255, 0, 0)
Silver	(192, 192, 192)
Teal	( 0, 128, 128)
White	(255, 255, 255)
Yellow	(255, 255, 0)

## Some Common Colors

# Frames per Second (FPS)

---

`clock.tick(30)` sets pygame's loop to run at a speed of **about** 30 frames/sec (FPS)

A frame = one game loop:

- handle events, update game state, redraw game

30 FPS = 30 frames (loops) in 1 second

so 1 frame (loop) =  $1/30$  sec  
=  $1000/30$  millisecs (ms)  $\approx 33$  ms

# Why Use FPS?

---

Games are easier to program if we know that one loop takes a fixed amount of time

- in our case, 1 loop = 33 ms

e.g. a game object that should be on-screen for 5 seconds will need to be drawn in 150 ( $30 \times 5$ ) loops

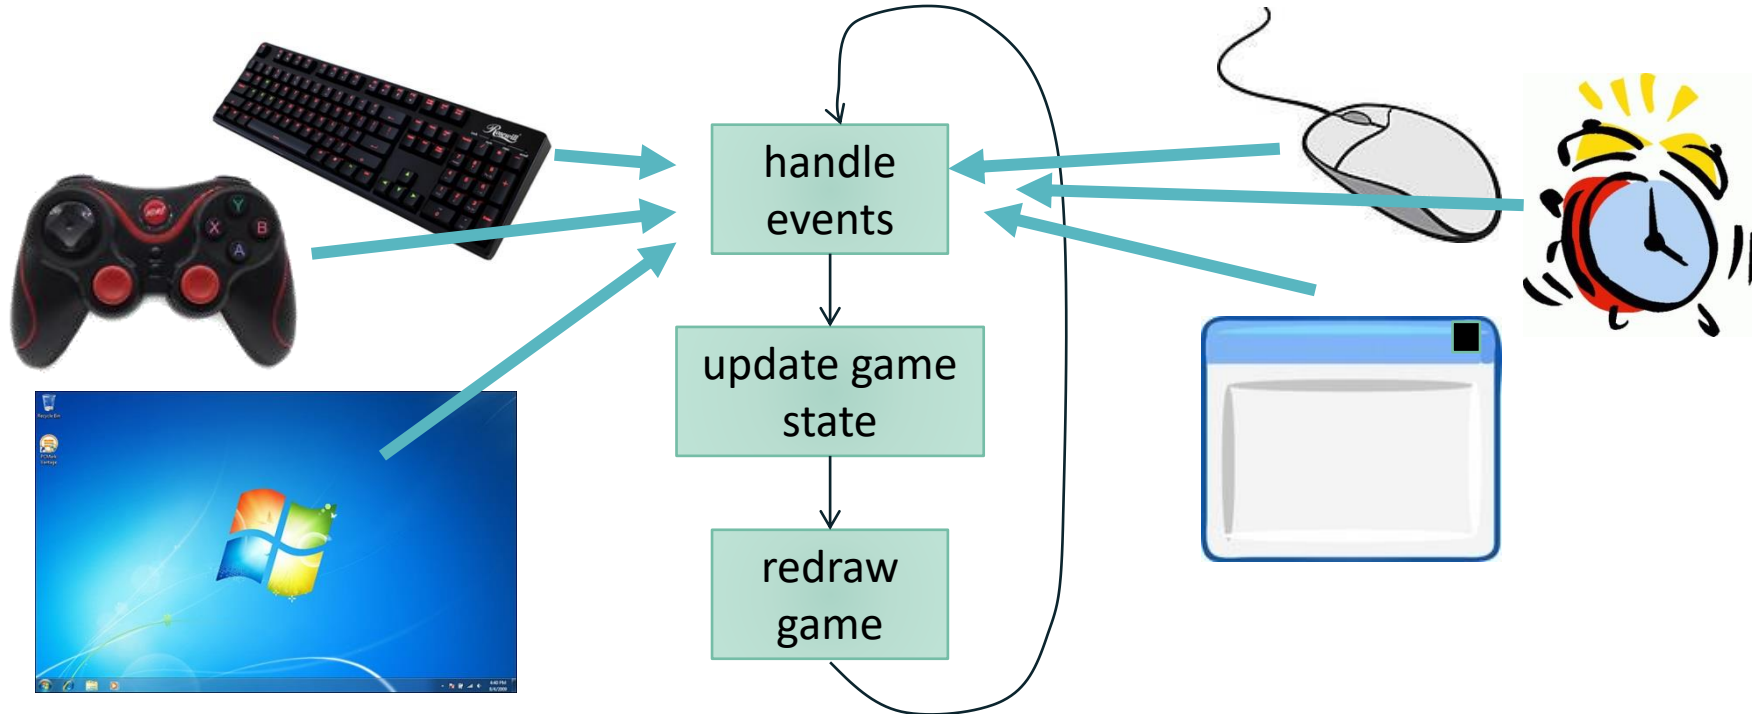

- 1 sec == 30 FPS
- 5 secs ==  $30 \times 5$  == 150

# Events

- An event is a user action (e.g. mouse or key press), or a computer change (e.g. clock tick).
  - a bit like "messages" sent to Pygame from the user and computer

# The "quit" event

---

```
for event in pygame.event.get():  
    if event.type == QUIT:      # user clicks close box  
        running = False
```

When running is false, the game loop ends, and Pygame quits.

# Quit by Also Typing <Esc>

---

```
for event in pygame.event.get():  
    if event.type == QUIT:          # user clicks close box  
        running = False  
  
    if (event.type == KEYUP and event.key == K_ESCAPE):  
        running = False  
                                     # user clicks <ESC> key
```

# Keyboard Events

---

- KEYDOWN is sent when a key is pressed
- KEYUP is sent when a key is released
- Each key has a constant that begins with K\_:
  - alphabet keys are K\_a through K\_z
  - Others: K\_SPACE, K\_RETURN, K\_ESCAPE, etc.
- For a complete list see
  - <http://www.pygame.org/docs/ref/key.html>

```

<Event<1-ActiveEvent {'state': 1, 'gain': 0}>>
<Event<12-Quit {}>>
>
```

## Other Events

Add `print(event)` to for-loop to see many events arriving at game loop.

# GUI and TUI

---

LECTURE 2

# Pygame Basics

---

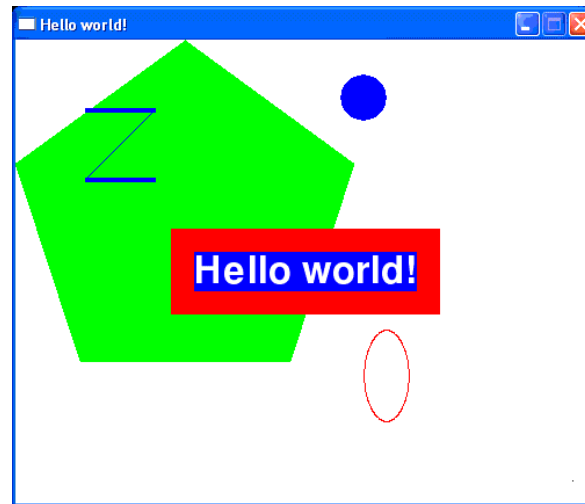

Just like how Python comes with several modules that provide additional functions for your programs (like math and random), the Pygame framework includes several modules with functions for:

- drawing graphics (Graphics – GUI and Canvas)
- playing sounds (Audio)
- handling mouse input (Event Handling)
- And more!

# Some Pygames

---

# GUI vs. TUI

---

The Python programs that you can write with Python's built-in functions only deal with text through the `print()` and `input()` functions.

Your program can display text on the screen and let the user type in text from the keyboard. This type of program has a command line interface, or TUI (Text-mode User Interface).

# GUI vs. TUI

---

These programs are somewhat limited because they can't display graphics, have colors, or use the mouse.

These CLI programs only get input from the keyboard with the `input()` function and even then user must press Enter before the program can respond to the input.

This means **real-time** (that is, continuing to run code without waiting for the user) action games are impossible to make.

# GUI vs. TUI

---

Pygame provides functions for creating programs with a *graphical user interface*, or **GUI** (pronounced, “gooey”).

Programs with a graphics-based GUIs can show a window with images and colors.

# PyGame Hello World

---

LECTURE 1

# Hello World

---

Our first program using Pygame will be a small program that makes a window that says

**“Hello World!”** appear on the screen.

# Blank Game

Demo Program: `blankgame.py`

1. Create a script called **blankpygame.py**
2. Type in the following program (do not include numbers or the periods at the beginning of the line – they are just for reference.)

Event Loop started.

Get one Event object  
from the event Loop.

Event Loop stopped.

```
import pygame
import sys

width, height = 240, 480

def main():
    pygame.init()
    root = pygame.display.set_mode((width, height))
    pygame.display.set_caption('Hello World!')
    while True:
        for event in pygame.event.get():
            if event.type == pygame.QUIT:
                pygame.quit()
                sys.exit()
        pygame.display.update()
    pygame.quit()

if __name__ == "__main__":
    main()
```

# Hello World

---

It's just a blank window with “Hello World!” at the top of the window (in what is called the window's **title bar**, which holds the **caption** text).

But creating a window is the first step to making graphical games. When you click on the X button in the corner of the window, the program will end and the window will disappear.

# Hello World – A Closer Look

---

```
1. import pygame, sys
```

The first few lines of code are lines that will begin almost every program you write that uses Pygame.

Line 1 is a simple import statement that imports the pygame and sys modules so that our program can use the functions in them.

All of the Pygame functions dealing with graphics, sound, and other features that Pygame provides are in the pygame module.

# Hello World

---

We can't use the `input()` or `print()` functions in a Pygame GUI. We will learn more about input and output in Pygame later.

Let's take a closer look to the "Hello World" program!

# Hello World – A Closer Look

---

```
2. from pygame.locals import *
```

Line 2 is also an import statement. It uses the form **modulename** import \* format.

Normally if you want to call a function that is in a module, you must use the **modulename.functionname()** format after importing the module.

However, with from **modulename** import \*, you can skip the **modulename.** portion and simply use functionname() (just like Python's built-in functions).

# Hello World – A Closer Look

---

## 4. `pygame.init()`

Line 4 is the `pygame.init()` function call, which always needs to be called after importing the `pygame` module and before calling any other Pygame function.

You don't need to know what this function does, you just need to know that it needs to be called first in order for many Pygame functions to work.

If you ever see an error message like

*`pygame.error: font not initialized,`*

check to see if you forgot to call `pygame.init()` at the start of your program.

# Hello World – A Closer Look

---

```
8      root = pygame.display.set_mode((width, height))
```

Line 5 is a call to the `pygame.display.set_mode()` function, which returns the `pygame.Surface` object for the window. *More on surface objects later...*

Notice that we pass a tuple value of two integers to the function: `(240, 480)`. This tuple tells the `set_mode()` function how wide and how high to make the window in pixels. `(240, 480)` will make a window with a width of 240 pixels and height of 480 pixels.

NOTE: An error will occur if it is not a tuple.

# Hello World – A Closer Look

```
6. pygame.display.set_caption('Hello World!')
```

Line 6 sets the caption text that will appear at the top of the window by calling the `pygame.display.set_caption()` function. The string value `'Hello World!'` is passed in this function call to make that text appear as the caption:

# Hello World – A Closer Look - Game States

---

```
7. while True: # main game loop
8.     for event in pygame.event.get():
```

Most of the games we will be looking at have these *while True* loops in them along with a comment calling it the “main game loop”. A game loop (also called a main loop) is a loop where the code does three things:

1. Handles events.
2. Updates the game state.
3. Draws the game state to the screen.

# The Game State

---

The **game state** is simply a way of referring to a set of values for all the variables in a game program. In many games, the game state includes the values in the variables that tracks the player's health and position, the health and position of any enemies, which marks have been made on a board, the score, or whose turn it is.

Whenever something happens like the player taking damage (which lowers their health value), or an enemy moves somewhere, or something happens in the game world we say that the game state has changed.

# The Game State

---

If you've ever played a game that lets you save, the "save state" is the game state at the point that you've saved it. In most games, pausing the game will prevent the game state from changing.

# The Game State

---

Since the game state is usually updated in response to events (such as mouse clicks or keyboard presses) or the passage of time, the game loop is constantly checking and re-checking many times a second for any new events that have happened. This is usually called event handling.

# Hello World – The QUIT Event

---

```
9.         if event.type == QUIT:
10.             pygame.quit()
11.             sys.exit()
```

Event objects have a member variable (also called attributes or properties – *remember ALICE?*) named `type` which tells us what kind of event the object represents.

Line 9 checks if the Event object's `type` is equal to the constant `QUIT`. Remember that since we used the `from pygame.locals import *` form of the import statement, we only have to type `QUIT` instead of `pygame.locals.QUIT`.

# Hello World – A Closer Look

---

```
12.     pygame.display.update()
```

Line 12 calls the `pygame.display.update()` function, which draws the Surface object returned by `pygame.display.set_mode()` to the screen (remember we stored this object in the `DISPLAYSURF` variable).

Since the Surface object hasn't changed, the same black image is redrawn to the screen each time `pygame.display.update()` is called.

## **pygame.display.flip()**

*Update the full display Surface to the screen*

```
flip() -> None
```

This will update the contents of the entire display.

## **pygame.display.update()**

*Update portions of the screen for software displays*

```
update(rectangle=None) -> None
```

```
update(rectangle_list) -> None
```

This function is like an optimized version of `pygame.display.flip()` for software displays. It allows only a portion of the screen to be updated, instead of the entire area. If no argument is passed it updates the entire Surface area like `pygame.display.flip()`.

# Hello World – That is IT!

---

That is the entire program!

After line 12 is done, the infinite while loop starts again from the beginning.

This program does nothing besides make a black window appear on the screen, constantly check for a QUIT event, and then redraws the unchanged black window to the screen over and over again.

# What is Next?

---

Let's learn how to make interesting things appear on this window instead of just blackness by learning about :

- Pixels
- Surface objects
- Color objects
- Rect objects
- Keyboard Mouse
- Pygame drawing functions.

# PyGame Click Ticks

---

LECTURE 3

# Separate the Data Unit and Control Unit

---

- The main function (also the view of the program) is separated from the game data unit (`data_init()`).
- In this way, we can deal with the graphic user interface and the data model much more efficiently.

# Adding clock ticks

---

We set the game cycle time to be 300 ticks (milli-sec) by setting `cycle_time = 300`.

For every `cycle_time`, we redraw the game board once. We will use print out to show how the program update every one cycle time.

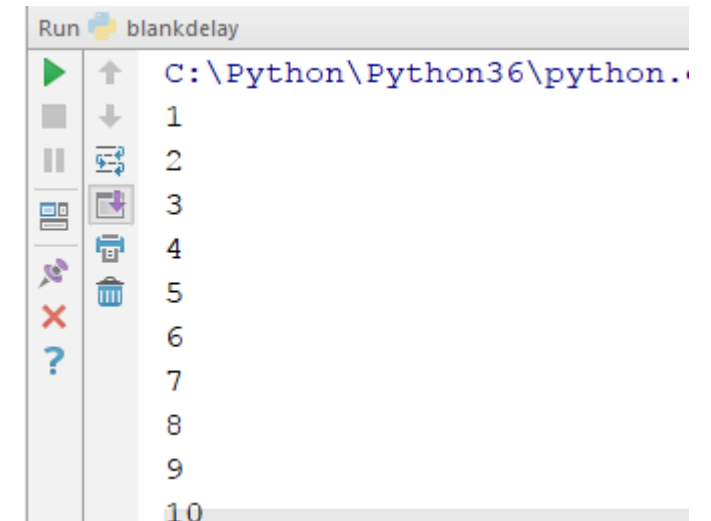

# Cycle Time

Demo Program: `blankdelay.py`

---

1. Add `cycle_time = 300`
2. update `pygame.display.update()` every one cycle time.
3. When updated, we advance a global counter by 1.

## Constants and Data Model

```
width, height = 240, 480
cycle_time = 300

# game data
count = 0
```

```
def data_init():
    global count
    count = 0
```

## Controller and View Model

```
def main():
    global width, height, cycle_time, count
    # initialize game board and other data
    data_init()

    pygame.init()
    root = pygame.display.set_mode((width, height))
    pygame.display.set_caption('Hello World!')
    while True:
        for event in pygame.event.get():
            if event.type == pygame.QUIT:
                pygame.quit()
                sys.exit()
        pygame.display.update()
        pygame.time.delay(cycle_time)
        count = count + 1
        print(count)
```

Delay for one Cycle (300 ticks)

## **pygame.time.get\_ticks()**

get the time in milliseconds

**get\_ticks() -> milliseconds**

Return the number of milliseconds since pygame.init() was called. Before pygame is initialized this will always be 0.

## **pygame.time.wait()**

pause the program for an amount of time

**wait(milliseconds) -> time**

Will pause for a given number of milliseconds.

## **pygame.time.delay()**

pause the program for an amount of time

**delay(milliseconds) -> time**

Will pause for a given number of milliseconds.

## **pygame.time.Clock**

create an object to help track time

**Clock()** -> **Clock**

pygame.time.Clock.tick

— update the clock

pygame.time.Clock.tick\_busy\_loop

— update the clock

pygame.time.Clock.get\_time

— time used in the previous tick

pygame.time.Clock.get\_rawtime

— actual time used in the previous tick

pygame.time.Clock.get\_fps

— compute the clock framerate

Creates a new Clock object that can be used to track an amount of time. The clock also provides several functions to help control a game's framerate.

Note: This clock object works like a timer.

# PyGame Adding Keyboard Events

---

LECTURE 4

Event Type	Event Attributes
QUIT	none
ACTIVEEVENT	gain, state
KEYDOWN	unicode, key, mod
KEYUP	key, mod
MOUSEMOTION	pos, rel, buttons
MOUSEBUTTONUP	pos, button
MOUSEBUTTONDOWN	pos, button
JOYAXISMOTION	joy, axis, value
JOYBALLMOTION	joy, ball, rel
JOYHATMOTION	joy, hat, value
JOYBUTTONUP	joy, button
JOYBUTTONDOWN	joy, button
VIDEORESIZE	size, w, h
VIDEOEXPOSE	none
USEREVENT	code

# Event Methods

<code>pygame.event.pump</code>	— internally process pygame event handlers
<code>pygame.event.get</code>	— get events from the queue
<code>pygame.event.poll</code>	— get a single event from the queue
<code>pygame.event.wait</code>	— wait for a single event from the queue
<code>pygame.event.peek</code>	— test if event types are waiting on the queue
<code>pygame.event.clear</code>	— remove all events from the queue
<code>pygame.event.event_name</code>	— get the string name from an event id
<code>pygame.event.set_blocked</code>	— control which events are allowed on the queue
<code>pygame.event.set_allowed</code>	— control which events are allowed on the queue
<code>pygame.event.get_blocked</code>	— test if a type of event is blocked from the queue
<code>pygame.event.set_grab</code>	— control the sharing of input devices with other applications
<code>pygame.event.get_grab</code>	— test if the program is sharing input devices
<code>pygame.event.post</code>	— place a new event on the queue
<code>pygame.event.Event</code>	— create a new event object

Quit	On Quit, the game program should be terminated.
Key down	On key down, we should accept the input by the user.
Key up	On key up, we should activate the update of data model and game board status.

```
while True:
    for event in pygame.event.get((pygame.KEYDOWN, pygame.KEYUP, pygame.QUIT)):
        if event.type == pygame.QUIT:
            pygame.quit()
            sys.exit()
        elif event.type == pygame.KEYDOWN:
            if event.key == pygame.K_DOWN:
                cycle_time = delay
                continue
            elif event.key == pygame.K_SPACE:

    main()
```

# PyGame Rectangles

---

LECTURE 6

# PyGame Color

---

- It is represented using the RGB (**Red**, **Green**, **Blue**) color model.
- In Python, we use tuples of 3 integers to represent the values of **red**, **green**, and **blue** each range from 0 to 255.
- In the following example, we just try to demonstrate how to draw simple rectangles, so we don't use Color Object from PyGame

# 13 Simple colors in a color dictionary

---

```
|color = {'BLACK': (0, 0, 0),  
         'WHITE': (255, 255, 255),  
         'RED': (255, 0, 0),  
         'ORANGE': (255, 128, 0),  
         'YELLOW': (255, 255, 0),  
         'APPLE': (128, 255, 0),  
         'GREEN': (0, 255, 0),  
         'LAKE': (0, 255, 128),  
         'CYAN': (0, 255, 255),  
         'TEAL': (0, 128, 255),  
         'PURPLE': (128, 0, 255),  
         'MAGENTA': (255, 0, 255),  
         'DEEPPINK': (255, 0, 128)  
|}
```

# Draw Rectangle on a Surface

A 3 tuple data for a color

```
pygame.draw.rect(surface, color, (left, top, width, height))
```

Surface is like Canvas in other tools.  
You may draw your rectangle on it. It is the graphics data holder.

(x, y) = (left, top) Coordinates for the dot

Zero point (center point for  
 $\text{zero}[0] = \text{block\_size}/2$   
= 30 (in example program)  
 $\text{zero}[1] = \text{block\_size}/2$   
= 30 (in the example program)

# draw\_clear() function

---

- To paint a black color block on a certain cell. It will work like removing the block.

# Random Block Generator

Demo Problem: [blankblock.py](#)

---

1. When space key is hit, a block of random color (color\_code[0] to color\_code[9]) will be generated.
2. When p key is hit, all blocks will be cleared.

# Simple Sound Effects

---

LECTURE 7

# Adding Sound Effect to Your Code

---

```
# Loading and playing background music:  
pygame.mixer.music.load(backgroundmusic.mp3')  
pygame.mixer.music.play(-1, 0.0)  
# ...some more of your code goes here...  
pygame.mixer.music.stop()
```

# Audio Effect tada.mp3 (1700+ ticks)

# pygame.mixer.music.play()

---

- Start the playback of the music stream
- `play(loops=0, start=0.0)` -> None
- This will play the loaded music stream. If the music is already playing it will be restarted.
- The loops argument controls the number of repeats a music will play. `play(5)` will cause the music to be played once, then repeated five times, for a total of six. If the loops is -1 then the music will repeat indefinitely.
- The starting position argument controls where in the music the song starts playing. The starting position is dependent on the format of music playing. MP3 and OGG use the position as time (in seconds). MOD music it is the pattern order number. Passing a startpos will raise a `NotImplementedError` if it cannot set the start position

```
1 import pygame
2 import sys
3
4 width, height = 240, 480
5
6 def main():
7     pygame.init()
8     root = pygame.display.set_mode((width, height))
9     pygame.display.set_caption('Hello World!')
10    pygame.mixer.music.load('tada.mp3')
11    pygame.mixer.music.play(-1, 0.0)
12    pygame.time.delay(1500)
13    pygame.mixer.music.stop()
14    while True:
15        for event in pygame.event.get():
16            if event.type == pygame.QUIT:
17                pygame.quit()
18                sys.exit()
19            pygame.display.update()
